

# Electrolysis of aqueous solutions

$H^+$  Aqueous solutions are **dissolved** in **water**. So in addition to the ions from the salt, the ions from the water molecules also have to be considered.

$OH^-$  Water molecules ionise (or split) to form hydrogen ions ( $H^+$ ) and hydroxide ions ( $OH^-$ ).

$H^+$  During the electrolysis of aqueous solutions the fate of these ions also needs to be considered.

## Electrolysis of sodium chloride solution

$OH^-$  Sodium chloride ionises in water to form positive sodium ions ( $Na^+$ ) and negative chloride ions ( $Cl^-$ ).

$H^+$  There are four ions in the aqueous solution. The two positive ions will be attracted to the negative electrode (cathode). These are  $H^+$  and  $Na^+$ . The two negative ions will be attracted to the positive electrode (anode). These are  $OH^-$  and  $Cl^-$ .

$OH^-$  The reactivity series is used to work out which ion will react at the electrode.

$H^+$  **Hydrogen** will be produced at the negative electrode (cathode) if the **metal** is **more reactive** than hydrogen.

$OH^-$  **Sodium** is **more reactive** than **hydrogen**, so hydrogen will be produced at the negative electrode (cathode).

$H^+$  If the aqueous solution contains **halide ions** (e.g.  $F^-$ ,  $Cl^-$ ,  $Br^-$  or  $I^-$ ), then the **halogen** will be produced at the **positive electrode** (anode). As a result, chlorine will be produced at the positive electrode.

sodium  
magnesium  
carbon  
zinc  
iron  
**hydrogen**  
copper

# Electrolysis of aqueous solutions...

## Half equations for electrolysis of sodium chloride

$\text{H}^+$  At the negative electrode (cathode):  $2\text{H}^+ + 2\text{e}^- \xrightarrow{\text{reduction}} \text{H}_2$

$\text{OH}^-$  At the positive electrode (anode):  $2\text{Cl}^- - 2\text{e}^- \xrightarrow{\text{oxidation}} \text{Cl}_2$

## Electrolysis of copper sulfate solution

$\text{OH}^-$  Copper sulfate ionises in water to form positive copper ions ( $\text{Cu}^{2+}$ ) and negative sulfate ions ( $\text{SO}_4^{2-}$ ).

$\text{H}^+$  There are four ions in the aqueous solution. The two positive ions will be attracted to the negative electrode (cathode). These are  $\text{H}^+$  and  $\text{Cu}^{2+}$ . The two negative ions will be attracted to the positive electrode (anode). These are  $\text{OH}^-$  and  $\text{SO}_4^{2-}$ .

$\text{OH}^-$  The reactivity series is used to work out which ion will react at the electrode.

$\text{H}^+$  **Hydrogen** will be produced at the negative electrode (cathode) if the **metal** is **more reactive** than hydrogen.

$\text{OH}^-$  **Copper** is **less reactive** than **hydrogen**, so copper will be produced at the negative electrode (cathode).

sodium  
magnesium  
carbon  
zinc  
iron  
**hydrogen**  
copper

$\text{H}^+$  If the aqueous solution does not contain halide ions then oxygen will be produced at the positive electrode by the  $\text{OH}^-$  ions.

## Half equations for electrolysis of copper sulfate

$\text{H}^+$  At the negative electrode:  $\text{Cu}^{2+} + 2\text{e}^- \xrightarrow{\text{reduction}} \text{Cu}$

$\text{OH}^-$  At the positive electrode:  $4\text{OH}^- - 4\text{e}^- \xrightarrow{\text{oxidation}} \text{O}_2 + 2\text{H}_2\text{O}$
