

Tip #6

Use relational APIs to identify elements.

Swipe next >

How to Do This?

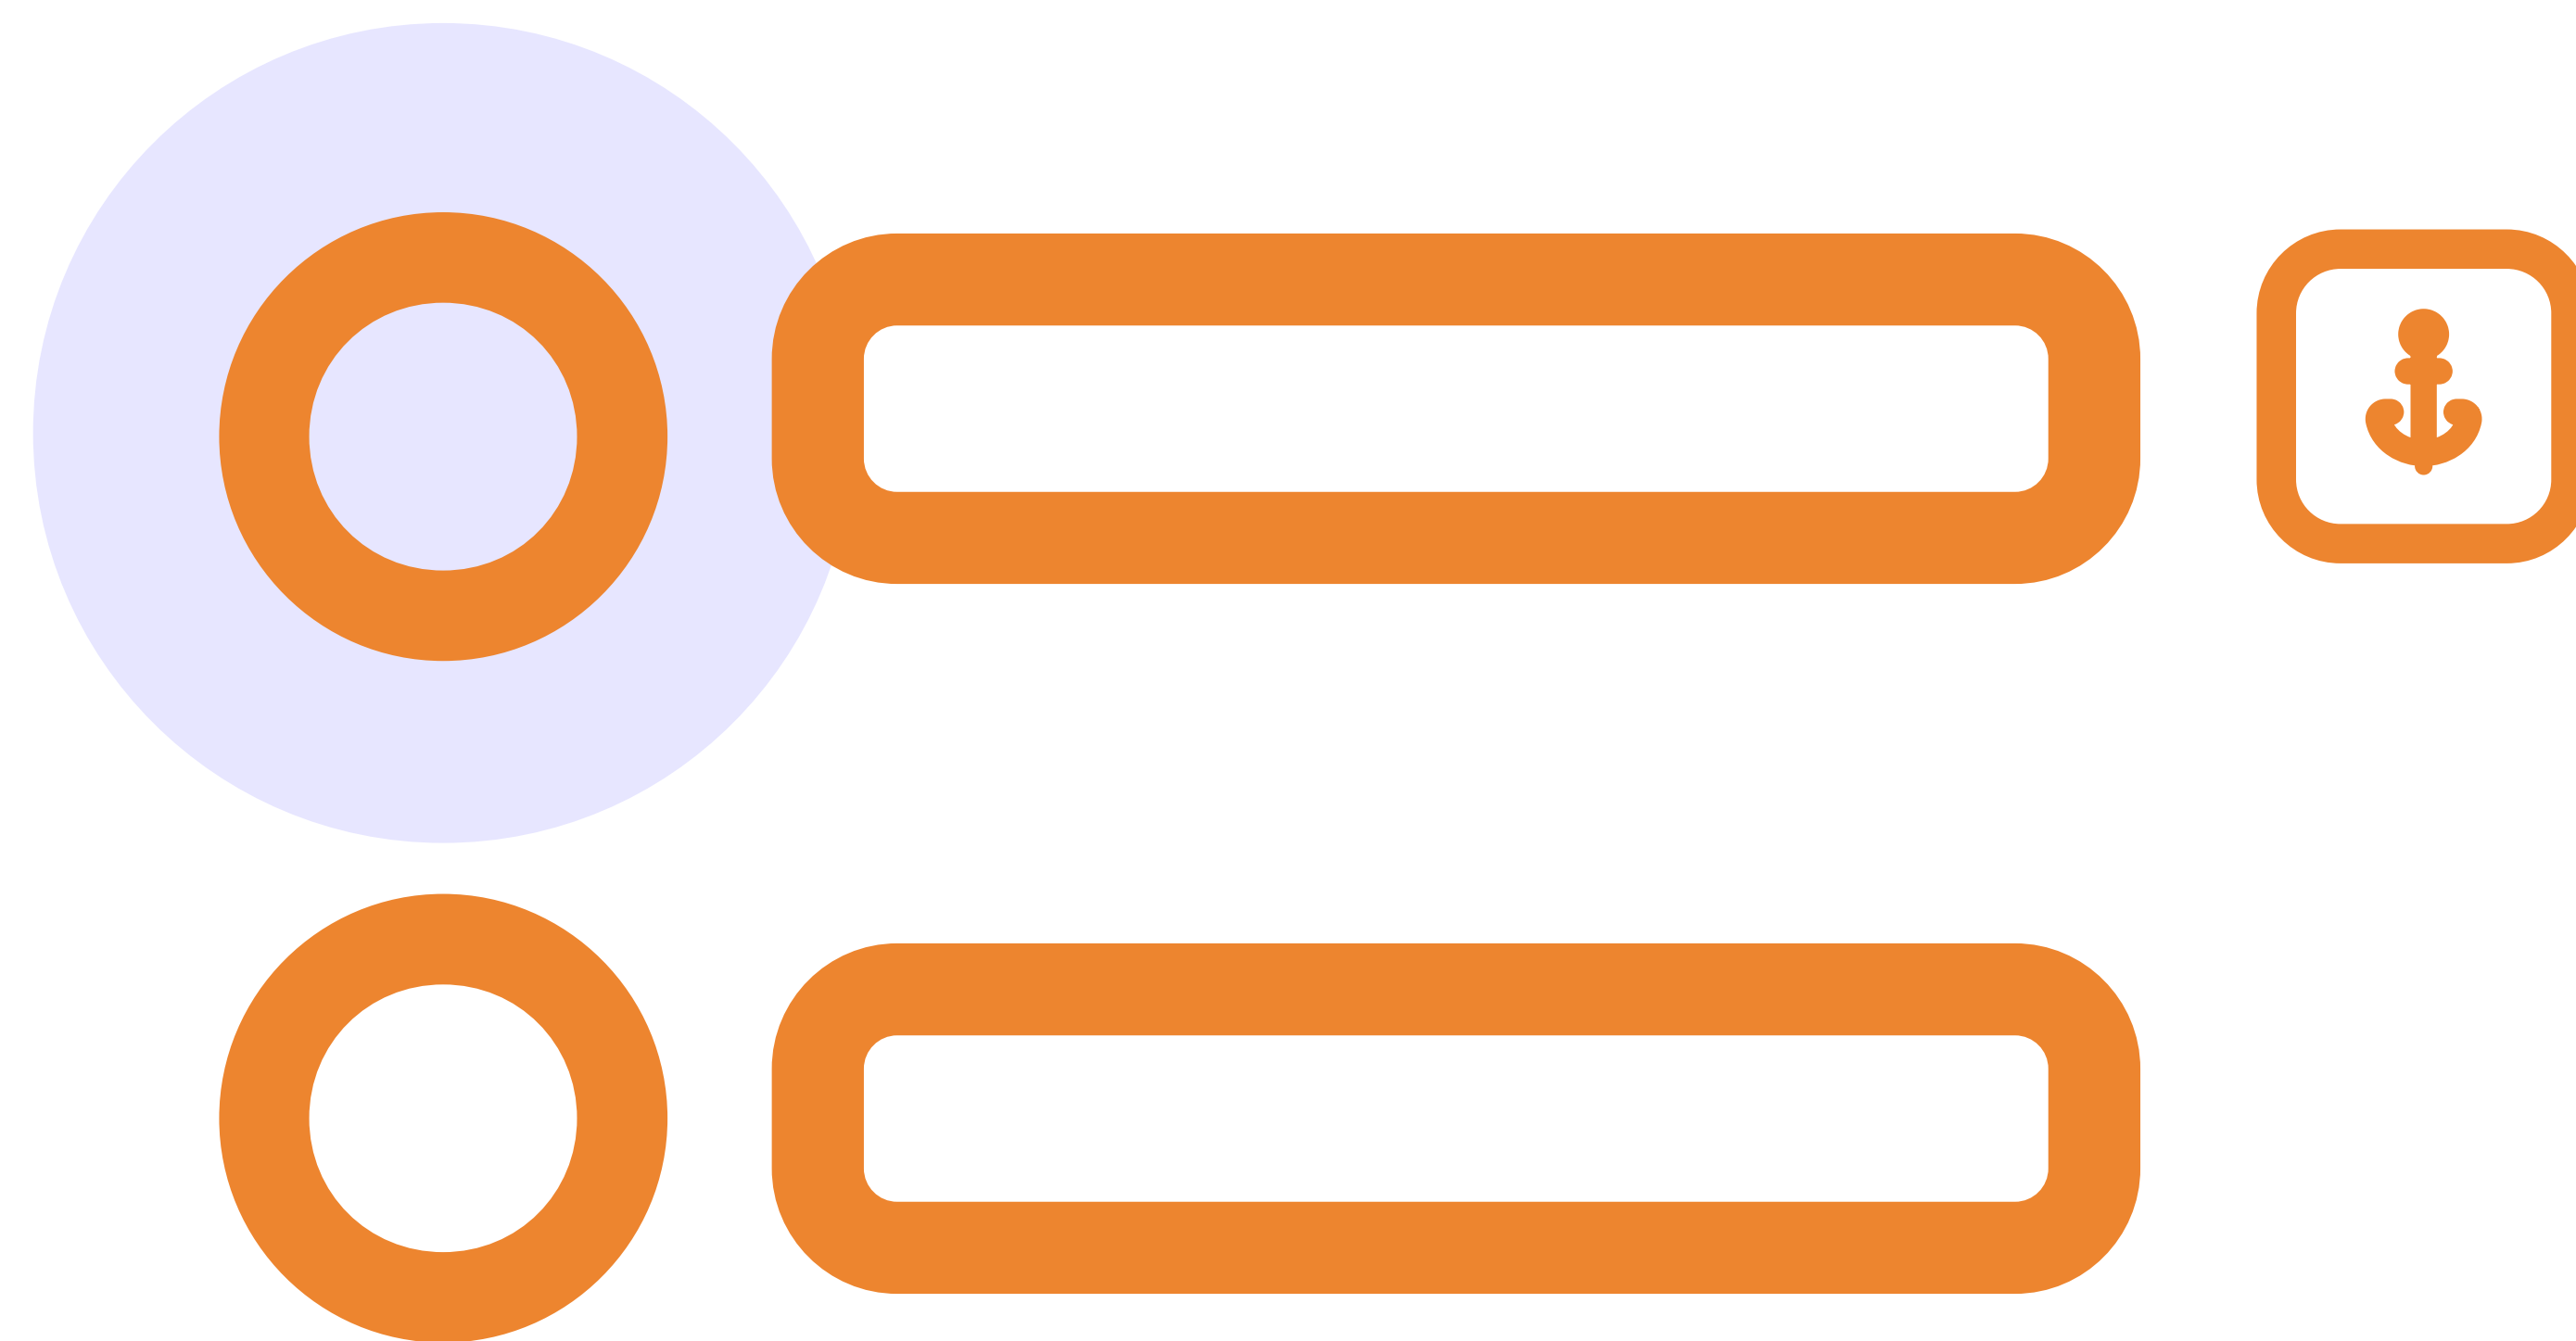

Let's say, Element1 does not have a unique identifier. Identify another element, let's say Element2, with a unique identifier.

Element2 must have a relation like **under/above/right/left/in/near** with Element1.

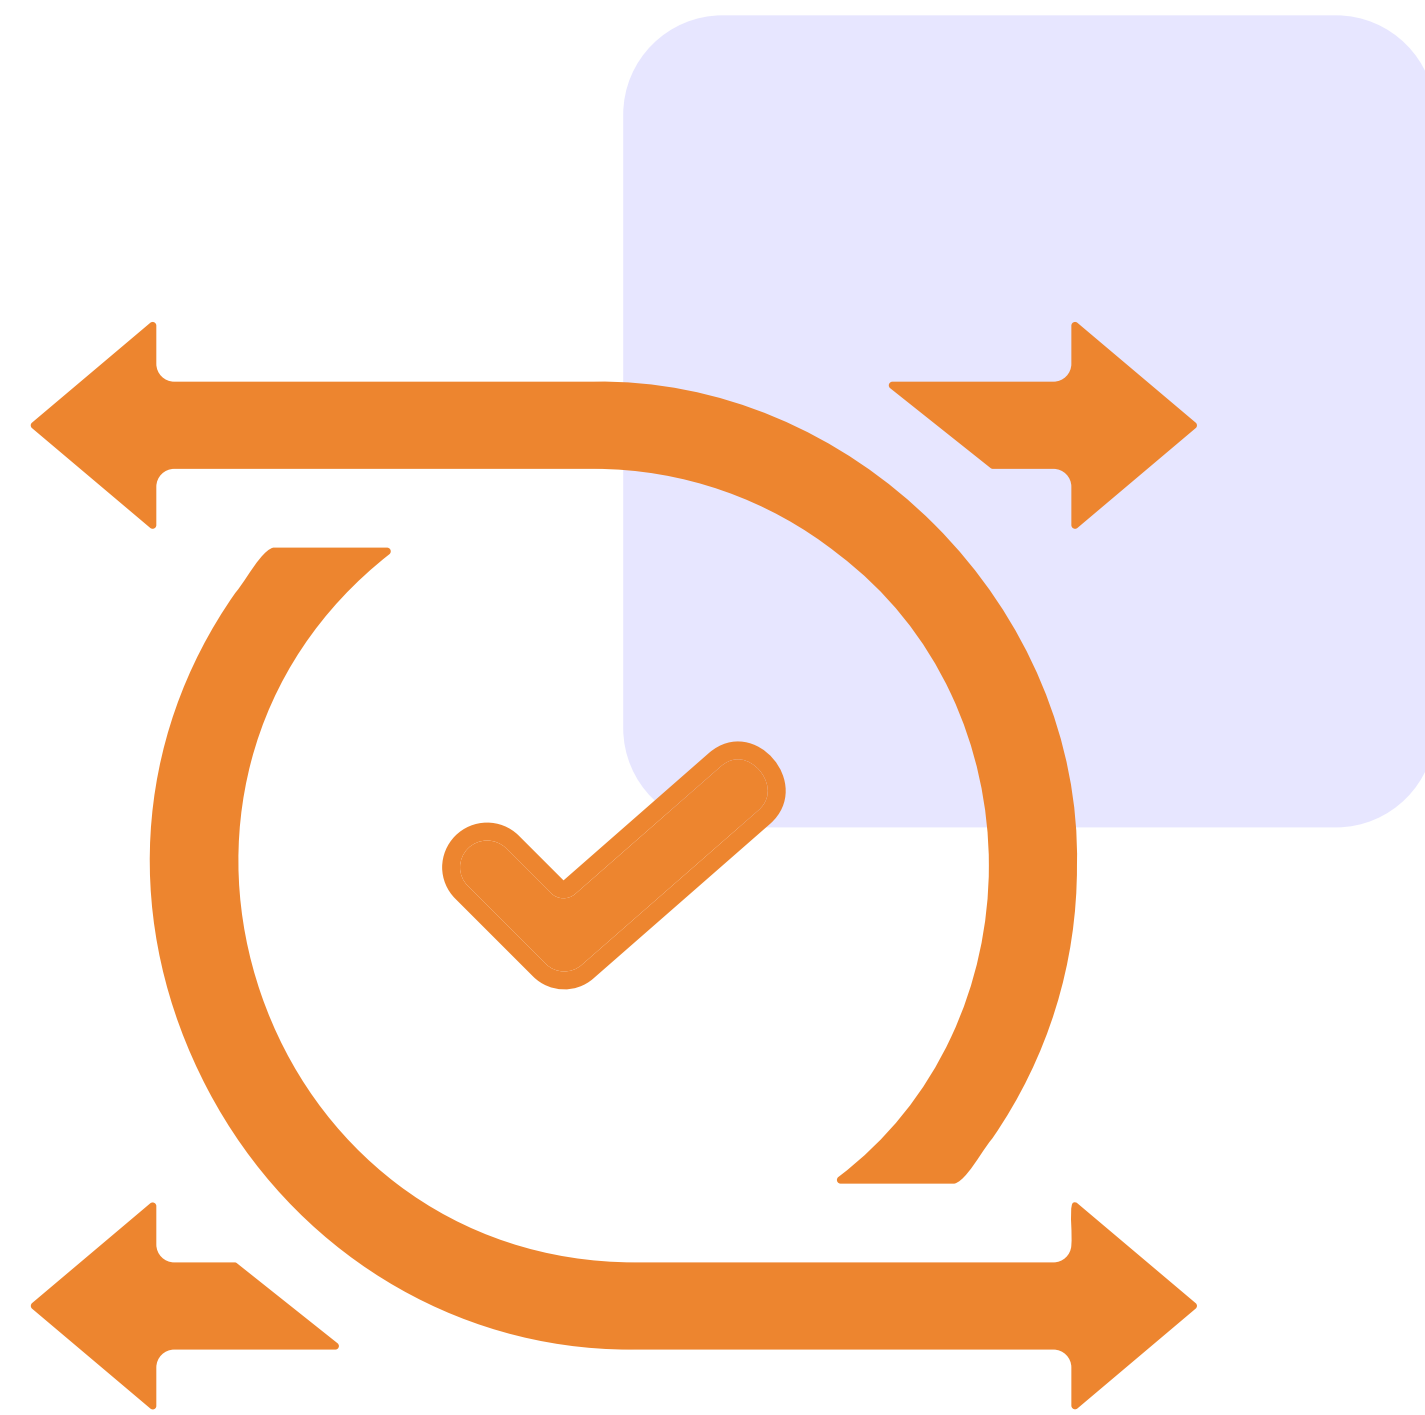

Then in the Sahi Pro Controller, **click on the anchor button.**

Next **identify the Element1**. Now, you will have an Accessor for Element1 in relation to Element2.

How Does this Benefit Anyone?

Using relational APIs **makes your scripts more foolproof and run consistently** even if the identifier changes.
